Adobe .Protecting Cichlid Fish from the Effects of Entomopathogenic Fungus Myrmecocystus meleagridis. African cichlid fish were exposed to either the entomopathogenic fungus Myrmecocystus meleagridis Kye et Tal. (Pucciniomycotina, Entomophthorales), or a combination of Aphanomyces astaci Hering & Fitch. (Oomycota, Agaricomycotina) and M. meleagridis. None of the fungus treatments significantly affected fish during a 90 d. trial, except for a slight, yet significant, delay in larval hatching in the fish exposed to the combination of fungi. Monitoring of cage-reared fish over a 12 mo. trial revealed that the mild weakness previously recorded in fish exposed to M. meleagridis did not last beyond the fourth week of the trial. The susceptibility of wild-caught fish to the entomopathogenic fungus was then tested by treating 21 fish in a 2-d bioassay, and subsequently recording larval hatching from eggs incubated in the fungal-treated water. The proportion of fish showing hatch was not significantly different from that of control fish (67 and 69% for M. meleagridis and M. astaci, respectively). This indicates that wild-caught cichlid fish were not as susceptible to M. meleagridis as fish raised under controlled conditions. These findings are discussed in light of their significance to cichlid fish farming in both captive and wild settings. Isoform-specific recruitment of CHD5 to cohesin mediates chromatid cohesion and chromosome segregation during cell division. The chromatinbinding protein cohesin contributes to chromosome cohesion and segregation, and is essential for embryonic development. Humans contain four cohesin genes encoding the structural maintenance of chromosomes (SMC)
